Introducing - The Magnitude

- Basic definition of magnitude from relative brightness of stars.
- The difference in magnitude between two stars, 1 and 2, with apparent brightnesses (as we see/observe) them in the sky, s_1 and s_2 , is given by

$$
m_1 - m_2 = -2.5 \log \left(\frac{s_1}{s_2} \right)
$$

• If a star at distance r has a surface luminosity of L_{λ} in wavelength λ a radiation flow of

$$
f_{\lambda} = \frac{L_{\lambda}}{4\pi r^2}
$$

reaches us.

and in

- ④ 伊 ≯ ④ 重 ≯ ④ 重

 QQ

The Magnitude

If our instrument, filer, or eye has a response function E_{λ} we obtain

$$
s=\frac{1}{4\pi r^2}\int_0^\infty L_\lambda E_\lambda \text{d}\lambda
$$

• The magnitude is then given, up to a constant, by

$$
m = -2.5 \log \frac{1}{4\pi r^2} \int_0^\infty L_\lambda E_\lambda \mathrm{d}\lambda + \mathrm{const.}
$$

Filters, Color Index

Filter Functions, arbitrary units (should be normalized to 1)

[The Magnitude](#page-2-0) [Filter and Colors](#page-4-0) [Absolute Magnitude and Distance Modulus](#page-5-0)

> • We define a color index by $m_x - m_y$ for filters x and y by

> > color index = $m_x - m_y$

 \bullet x, y is, e.g., "U", "B", "V" for ultraviolet, blue, and visible.

つくへ

- They have centers at $\lambda_{\text{U}} = 365$ nm.
	- $\lambda_{\rm B} = 440$ nm, and $\lambda_{\rm V}$ = 584 nm.

イロメ イ母メ イヨメ イヨメ

 209

Absolute Magnitude, Distance Modulus

• We often define

 $U = m_{\rm B}$, $B = m_{\rm B}$, and $V = m_{\rm B}$, etc.

- \bullet We define the absolute magnitude M of a star by its apparent magnitude if it were at a distance of 10 pc $(1 pc = 3.26$ light years)
- With this definition we obtain the distance modulus by

$$
m-M=5\log\left(\frac{r}{10\,\text{pc}}\right)
$$

The bolometric luminosity is the total luminosity of a star through its entire spectrum, i.e., $E_{\lambda} = 1$.

 $\langle \bigcap \mathbb{P} \rangle$ \rightarrow $\langle \bigcap \mathbb{P} \rangle$ \rightarrow $\langle \bigcap \mathbb{P} \rangle$

つくへ

Absolute Bolometric Magnitude

- The apparent bolometric luminosity of the sun is $m_{\text{bol},\odot} = -26.83 \text{ Mag}$
- The bolometric correction, B.C., is defined by $B.C. = m_B - m_{bol}$
- The absolute magnitude of the sun is $M_{\text{bol},\odot} = 4.74 \text{ Mag}$
- The absolute bolometric magnitude of a star is hence given by

$$
\textit{M}_{\text{bol}} = 4.74 - 2.5 \log \left(\frac{\textit{L}}{\textit{L}_{\odot}} \right) \ \ [\text{Mag}]
$$

Quiz

 \bullet

Starting from the definition of magnitude differences and the definition of the absolute magnitude, derive the formula for the distance modulus, $m - M$.

$$
m_1 - m_2 = -2.5 \log \left(\frac{s_1}{s_2} \right)
$$

 \bullet We define the absolute magnitude M of a star by its apparent magnitude if it were at a distance of 10 pc

Instructions:

- Work on this yourself and write down your solution (2min)
- Discuss in groups of 2-3 (2min)

Quiz - Solution

Starting from the definition of magnitude differences and the definition of the absolute magnitude, derive the formula for the distance modulus, $m - M$. Definition of magnitude differences:

$$
m_1-m_2=-2.5\log\left(\frac{s_1}{s_2}\right) ,
$$

where s_1 and s_2 are the apparent brightnesses (as we see/observe) them in the sky. The absolute magnitude M is the apparent magnitude at a distance of 10 pc. Hence the *distance modulus*, $m - M$ is the is the difference in apparent magnitude of the star if it were at a distance of 10 pc to its true (observed) magnitude. We also use the flux, i.e., the observed brightness drops according to the inverse square law, $1/d^2$ where d is the distance, replacing m_1 by m , m_2 by M, s_1 by s and s_2 by s \times $(d/10 \text{ pc})^2$ we obtain.

$$
m - M = -2.5 \log \left(\frac{s}{s \times (d/10 \text{ pc})^2} \right) = -2.5 \log \left(\left[\frac{10 \text{ pc}}{d} \right]^2 \right) = 5 \log \left(\frac{d}{10 \text{ pc}} \right)
$$

NOTE: Here we have neglected the effects of extinction, filter functions, and bolometric corrections, etc. イロメ イ何メ イヨメ イヨメー ヨ

Quiz - Solution

Compute the distance modulus of the sun.

The sun has a distance of one astronomical unit, 1.49598×10^{13} cm = 4.84813681 $\times10^{-6}$ pc. Hence we have

$$
(m-M)_{\odot} = 5 \log \left(\frac{4.84813681 \times 10^{-6} \text{ pc}}{10 \text{ pc}} \right)
$$

$$
(m-M)_{\odot}=5\log\left(4.84813681\times10^{-7}\right)=-31.57\,\text{Mag}
$$

Naming Ionization Levels

Ionization levels are named using capital roman letters:

- "I" corresponds to the neutral atom,
- "II" to the single ionized atom,
- "III" to the double ionized atom.
- and so forth.

Examples:

- Hell: single ionized helium
- FeXXVII: completely ionized iron
